

## Some white board writing from week 5

I continued lecturing about inference principles. I discussed the weak likelihood principle. I also presented an example with 3 different experiments that give rise to proportional likelihoods. These discussions are presented in details in the notes and I abstain from reproducing them here.

Then I introduced the notion of (Fisher) Information as the variance of the score: Information in the sample  $\mathbf{X} = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}$  of  $n$  i.i.d. observations from distribution with a density  $f(x, \theta)$ ,  $\theta \in \mathbb{R}^1$  as

$$I_{\mathbf{X}}(\theta) = \text{Var}_{\theta}(V(\mathbf{X}, \theta)) = E_{\theta} \left( \frac{\partial}{\partial \theta} \ln L(\mathbf{X}, \theta) \right)^2 =$$

$$= E_{\theta} \left( \sum_{i=1}^n \frac{\partial}{\partial \theta} \ln f(x_i, \theta) \right)^2.$$

I also discussed the properties of the Information quantity introduced above such as:

i) additivity over independent samples

ii) preservation of information by a sufficient statistic,  
i.e.  $I_T(\theta) = I_{\mathbf{X}}(\theta)$  when  $T$  is sufficient

iii) alternative way to calculate the information in the sample: under smoothness regularity conditions:

$$I_{\mathbf{X}}(\theta) = -E \left( \frac{\partial^2}{\partial \theta^2} \ln L(\mathbf{X}, \theta) \right)$$

iv) For any statistic  $T(\mathbf{X})$  it holds  $I_T(\theta) \leq I_{\mathbf{X}}(\theta)$ , with equality if and only if  $T(\mathbf{X})$  is sufficient for  $\theta$ .

I went through the proofs of all these statements but the proofs are thoroughly presented in the notes and I am not reproducing them here.

Then I started discussing unbiasedness and CR inequality.

1) First I discussed the relevance of the notion of unbiasedness: ②

Biased estimator

Unbiased estimator with high variance

Unbiased estimator with small variance

Thanks to the decomposition

$$MSE_{\theta}(T_n) = E_{\theta}(T_n - \theta)^2 = Var_{\theta} T_n + (b_n(\theta))^2$$

and the graphs above, it does make sense to look for the estimator with the smallest possible variance in the class of unbiased estimators.

I did make a cautious remark that sometimes an unbiased estimator may not be that useful. Take  $f(x, \theta) = \theta(1-\theta)^{x-1}$ ,  $x=1, 2, \dots$  &  $T(x)$  based on  $n=1$  observation would mean that  $\sum_{x=1}^{\infty} T(x)\theta(1-\theta)^{x-1} = \theta$  holds

$\forall \theta \in (0, 1)$ . Cancel  $\theta$  set  $\eta = 1-\theta$  and we see:  $T(1) + \eta T(2) + \eta^2 T(3) + \dots = 1 \quad \forall \eta \in (0, 1)$  must hold.

Hence  $T(1)=1$  and  $T(2)=T(3)=T(4)=\dots=0$ !

Note: the estimator  $\tilde{T}(x) = \frac{1}{x}$  (which happens to be the MLE in this example) is much more useful.

2) Example illustrating that when condition (x) is violated, we could have estimators which are unbiased and have a variance  $<$  C.R. bound:

Let  $X_1, X_2, \dots, X_n$  be i.i.d. uniform in  $[0, \theta]$  (so that the support of the density depends on  $\theta$  & (x) is violated)

$$f_{X_1}(x) = \frac{1}{\theta} I_{(0, \theta)}(x) \rightarrow F_{X_1}(x) = \begin{cases} 0 & x \leq 0 \\ \frac{x}{\theta} & 0 < x \leq \theta \\ 1 & x > \theta \end{cases} \quad \text{Then:}$$

$$F_{X_{(n)}}(y) = P(X_{(n)} \leq y) = P(X_1 \leq y \cap X_2 \leq y \cap \dots \cap X_n \leq y) = \left(\frac{y}{\theta}\right)^n, \quad 0 < y < \theta$$

$$\text{Hence } f_{X_{(n)}}(y) = \frac{ny^{n-1}}{\theta^n}, \quad 0 < y < \theta \text{ (and zero else)}$$

Take  $E X_{(n)} = \int_0^\theta y \frac{n y^{n-1}}{\theta^n} dy = \frac{n}{n+1} \theta \neq \theta$ , (3)  
 i.e.  $X_{(n)}$  is biased for estimating  $\theta$ . BUT:

$T = \frac{n+1}{n} X_{(n)}$  is unbiased for estimating  $\theta$ .

$$\text{Var } T = E(T^2) - \theta^2 = \left(\frac{n+1}{n}\right)^2 \int_0^\theta y^2 \frac{n y^{n-1}}{\theta^n} dy - \theta^2 = \dots = \frac{\theta^2}{n(n+1)}$$

But for  $f_{X_1}(\theta) = \frac{1}{\theta}, 0 < \theta$  we have  $\ln f_{X_1}(\theta) = -\ln \theta$

$$\frac{\partial}{\partial \theta} \ln f_{X_1}(\theta) = -\frac{1}{\theta} \quad E\left(\frac{\partial}{\partial \theta} \ln f_{X_1}(\theta)\right)^2 = \frac{1}{\theta^2} \text{ and}$$

reckless application of CR Bound would imply  
 CR Bound =  $\frac{\theta^2}{n}$ . As we see now:

$$\text{Var}(T) = \frac{\theta^2}{n(n+1)} < \frac{\theta^2}{n}$$

Reason for this seeming contradiction: the condition (\*) was violated in this example!

3) Score function for the Poisson( $\theta$ ) example:

$X_1, X_2, \dots, X_n$  i.i.d. Poisson( $\theta$ )

$$P(X_i = x) = \frac{e^{-\theta} \theta^x}{x!}, x = 0, 1, 2, \dots$$

$$L(\mathbf{X}, \theta) = \frac{e^{-n\theta} \theta^{\sum_{i=1}^n x_i}}{\prod_{i=1}^n x_i!} \quad \text{Hence}$$

$$V(\mathbf{X}, \theta) = \frac{\partial}{\partial \theta} \log L(\mathbf{X}, \theta) = -n + \frac{\sum_{i=1}^n X_i}{\theta}$$

If  $\tau(\theta) = \theta \rightarrow V(\mathbf{X}, \theta) = \frac{n}{\theta} (\bar{X} - \theta) \rightarrow$  factorization  
 possible and  $\bar{X}$  is the UMVUE of  $\theta$  that  
 attains the CR Bound
